

Duy Hoang
Task 6

Starting out with Prolog felt strange after spending so much time on something like Java. Instead of following steps one by one, it tries to figure things out through logic matches. Getting my head around recursion took a little while, mainly because the way it repeats feels less obvious here. Predicates were another new idea - like defining facts and letting the system find paths between them. The format of code sometimes threw me off, particularly how lists appear inside square brackets. Without clear stopping points in recursive definitions, rules kept looping unexpectedly. At first, even running programs caused hiccups due to the interactive nature of its interpreter. Each attempt revealed small clues about what went wrong last time. Gradually, pieces began connecting into a clearer picture of how this language thinks. Solving parts of the task slowly built up confidence in reading and shaping logical structures.
